

## **Main glitches:**

### **1. Host / co-host logic broken**

You could not make another participant co-host properly before the event started. Role permissions need fixing.

### **2. Round duration / timer broken**

Timers were not moving, were out of sync between users, and rounds ended suddenly. One person saw 27 seconds, another saw 6 seconds.

### **3. People were thrown in and out of rooms**

Users got bounced between lobby and breakout rooms, sometimes repeatedly.

### **4. Matching was tricky**

People were matched with users who were not there, late joiners were thrown straight into meetings, and absent users still appeared in match assignments.

### **5. Some users were alone in rooms**

Several participants reported being placed in rooms without their partner showing up. Or it said, waiting for your partner to join.

### **6. Sessions ended without warning**

People were cut off mid-conversation with no visible countdown, sound, warning, or transition notice.

### **7. Video layout is broken**

Compact, normal, and spacious modes behave badly. Spacious mode cuts people off and does not let users scroll to see everyone.

### **8. Chat UX is weak**

On mobile, chat was hard to find or missing. On desktop, chat was hidden far to the side. Clicking names/links in chat removed users from the event.

9. **Background feature unstable**

Adding/changing background kicked someone out. Blur/background also only partly worked for some users.

10. **Audio/mute behavior strange**

Echo was reported. Users could not always tell if their mic was working. Pinning someone may have muted them automatically.

11. **Rating flow unclear**

Users were unsure whether to rate because the sessions were broken and they worried it would skew the data.

This second talk confirms something important:

The system instability is not random anymore. It is systemic.

New glitches and observations from the follow-up debrief:

1. Final stretch logic broken  
The UI says users are entering “final stretch,” but nobody actually experiences the transition correctly. Timer freezes instead.
2. Rating system broken in group rooms  
In 3-person rooms, users only received one rating option instead of multiple participant ratings.
3. Massive wasted screen space  
The layout uses tiny participant boxes with excessive whitespace. The interface does not scale properly to screen size.
4. Spacious mode fundamentally broken  
At 13 participants, users could only see 4–5 people and could not scroll further.
5. Pinning someone may trigger mute logic  
Very important bug. Pinning participants appears connected to mute/unmute state changes. Users were being muted unexpectedly.
6. Auto mute behavior unstable  
Users trying to unmute themselves got re-muted automatically.
7. “Leave” button is dangerous UX  
There are two “leave” actions:
  - Leave breakout room
  - Leave entire event

Users cannot distinguish them. This causes accidental exits from the whole event. Claus correctly identified this as a UX architecture problem, not just a bug.

8. Participant count inconsistent  
System showed 8, then 12, then 13 participants. Actual attendance unclear.
9. Different users saw different realities  
Critical issue.

Some users saw pinned participants.

Others did not.

Some saw rooms.

Others saw empty rooms.

This means client synchronization is failing.

10. 25 users registered, only ~13 visible  
This is huge.

Possible causes:

- Presence sync failure
  - Failed room joins
  - LiveKit state issues
  - Ghost participants
  - Failed websocket reconnects
  - Users stuck in waiting state
11. “Waiting for...” state bug  
Users were matched with people who technically existed in the system, but were not actually present in the room.
  12. Regression problem  
This may actually be the most serious insight from the whole conversation.

Shradha points out that features previously working are becoming unstable again:  
“Every time it just gets different.”  
“We are back to square one.”

That usually means:

- weak event state architecture
  - race conditions
  - frontend/backend desync
  - insufficient automated testing
  - too many live patches
  - unstable LiveKit orchestration
  - no deterministic event engine
13. Navigation is too complicated  
Even internal testers now struggle navigating the platform. That means first-time users will absolutely struggle.
  14. Core insight from Claus  
This matters strategically:  
Users were still positive despite the chaos because the core concept is strong.

That is actually rare.

Most broken products get rejected immediately.  
People stayed emotionally engaged because the idea itself works.

My read:

You now have proof of three things:

1. The concept is real  
People clearly want this.

2. The event layer is your company right now  
Claus is correct. The event experience is the product.
3. Your current architecture is unstable under real-world concurrency  
You are now beyond “demo bugs.”  
This is now systems engineering territory.
